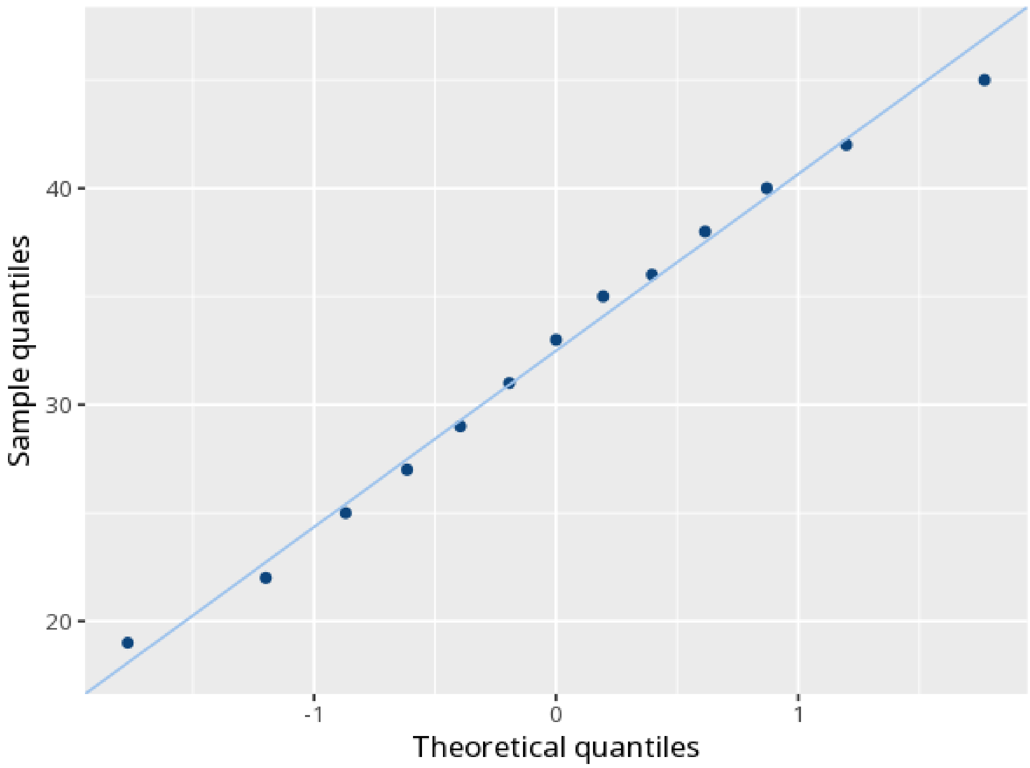
anxiety



A small p (below .05) suggests the data depart from normality. With large samples these tests over-flag trivial deviations; with small samples they have low power, so a $p > .05$ does not prove normality — it only means no departure was detected. Either way, judge normality mainly from the Q–Q plot — points hugging the diagonal indicate normality.

score: Normality was assessed with the Shapiro-Wilk test, W = .96, p = .679. anxiety: Normality was assessed with the Shapiro-Wilk test, W = .98, p = .990.

Statistical basis: Shapiro-Wilk test for normality (3-5000 cases) (Shapiro, S. S., Wilk, M. B. (1965). "An analysis of variance test for normality (complete samples)." Biometrika, 52(3/4), 591-611.); Additional normality tests (Lilliefors and related) (Gross J, Ligges U (2015). nortest: Tests for Normality. R package.).
