01 · CRONBACH'S ALPHA

internal consistency of one scale

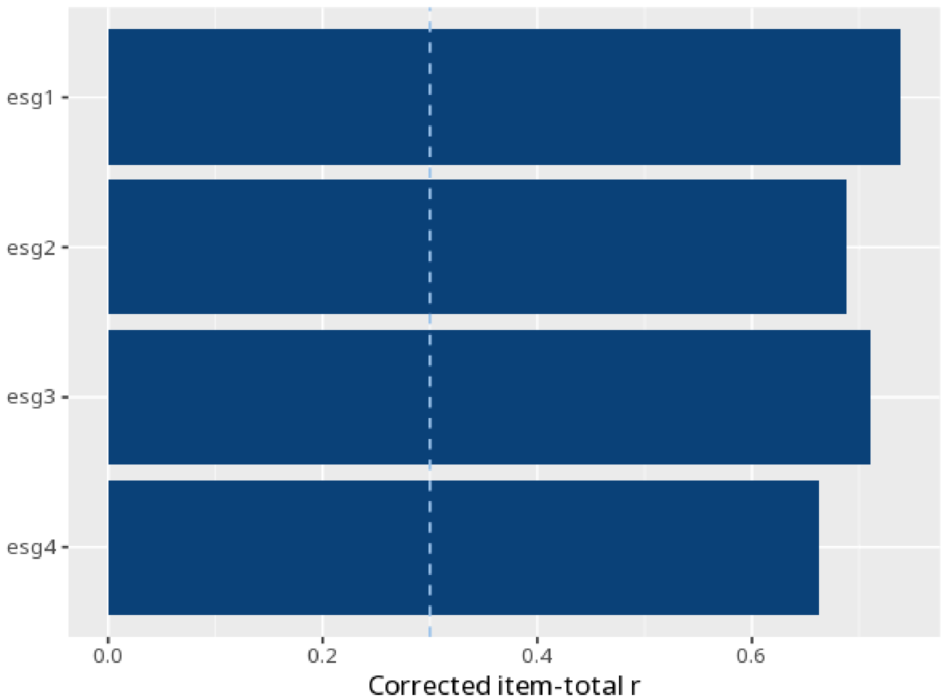
**Table 1.** Reliability

| ω | α | 95% CI | N items | N cases |
|---|---|---|---|---|
| .86 | .86 | [0.83, 0.88] | 4 | 400 |

**Table 2.** Item-total statistics

| Item | Corrected item-total r | α if item dropped |
|---|---|---|
| esg1 | 0.74 | .80 |
| esg2 | 0.69 | .82 |
| esg3 | 0.71 | .81 |
| esg4 | 0.66 | .83 |

**Figure.** Item contribution



## Understanding the numbers

**ω (omega).** The headline reliability coefficient for this scale - it only assumes a one-factor (congeneric) model, so it's preferred over α when item loadings differ (McNeish, 2018). Here, ω = .86, 95% CI [0.83, 0.88] - values ≥ .70 are commonly considered acceptable, ≥ .80 good, and > .95 may suggest item redundancy.

**α (Cronbach's alpha).** A secondary/legacy reliability coefficient that assumes every item loads equally (tau-equivalence); it is a lower bound on reliability when loadings differ. Here, α = .86.

**95% CI.** The range likely to contain ω's true value, given sampling variability. Here, the 95% CI for ω is [0.83, 0.88].

**N items.** The number of items making up this scale. Here, N items = 4.

**N cases.** The number of complete cases (participants) the estimates are based on. Here, N cases = 400.

**Corrected item-total r.** How strongly one item correlates with the sum of the remaining items - a diagnostic of whether it belongs on this scale. Each row is one item's own item-total correlation; a low or negative value flags an item that may not belong on this scale.

**α if item dropped.** What Cronbach's α would be if that one item were removed from the scale - it flags items worth reviewing. An item whose "α if item dropped" value is higher than the overall α (.86) is a candidate for review.

### How to read this test

ω (McDonald's omega) is the headline reliability coefficient; it assumes only a congeneric (one-factor) model and is preferred over α when item loadings differ (McNeish, 2018). α (Cronbach's alpha) assumes tau-equivalence (equal loadings) and is a lower bound when loadings differ; it is retained as a secondary/legacy coefficient because reviewers still request it. Both range 0–1; ≥ .70 is commonly considered acceptable, ≥ .80 good, > .95 suggests item redundancy — treat these as heuristics, not pass/fail thresholds. The "α if item dropped" column flags items that, if removed, would raise α — candidates for review. A high coefficient does not prove unidimensionality.

**APA template:** Internal consistency was good, ω=.86 (95% CI [0.83, 0.88]); Cronbach's α=.86.

**Statistical basis:** Cronbach's alpha (tau-equivalent reliability) (Revelle W (2024). psych: Procedures for Psychological, Psychometric, and Personality Research. Northwestern University, Evanston.); McDonald's omega as the headline reliability coefficient (preferred over alpha when loadings differ) (McNeish, D. (2018). "Thanks coefficient alpha, we'll take it from here." Psychological Methods, 23(3), 412-433.). Full references in the exported CITATIONS.txt.
