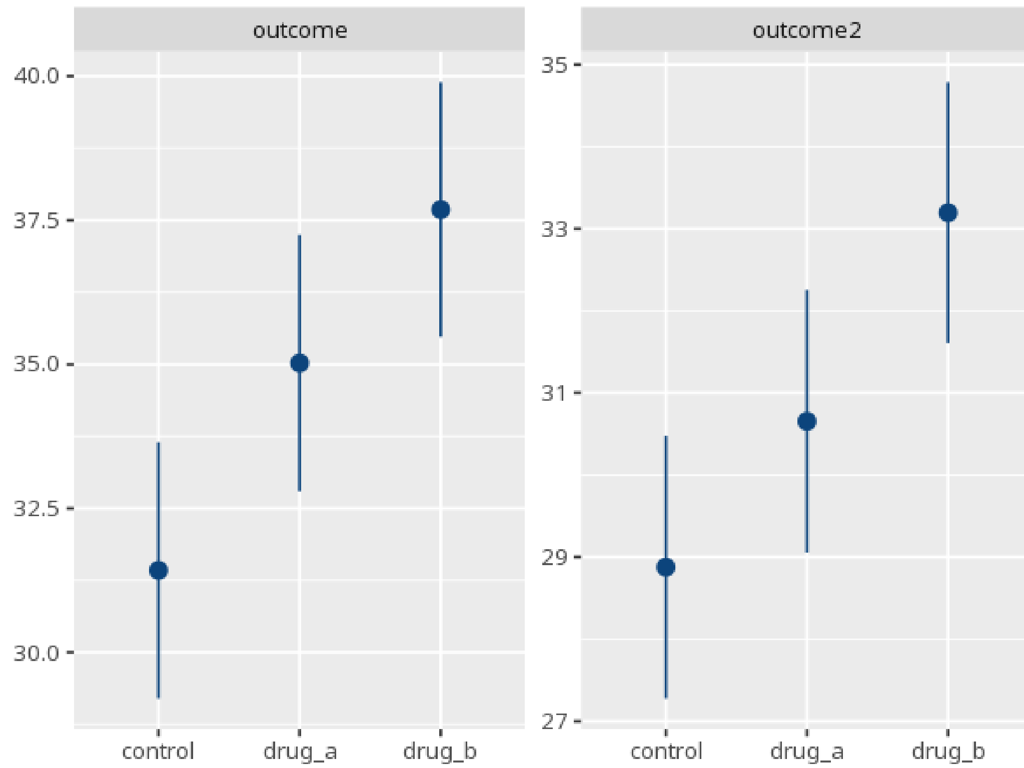
1 MANCOVA

Effect	Pillai / Wilks	approx F	df1	df2	p
baseline	0.55	33.87	2	55	<.001
group	0.37	6.30	4	112	<.001

DV	F	df1	df2	p	partial η^2 [95% CI]
outcome	8.07	2	56	<.001	0.22 [0.07, 1.00]
outcome2	7.47	2	56	.001	0.21 [0.06, 1.00]



Like MANOVA, but group differences on the set of outcomes are assessed after controlling for one or more covariates. Interpret the univariate follow-ups only if the multivariate p is significant, and adjust them for the number of DVs (e.g. Bonferroni) to control familywise error. Your significance threshold (α) is 0.05.

A MANCOVA gave a covariate-adjusted group effect, Pillai's V=.37, F(4,112)=6.30, p < .001.
