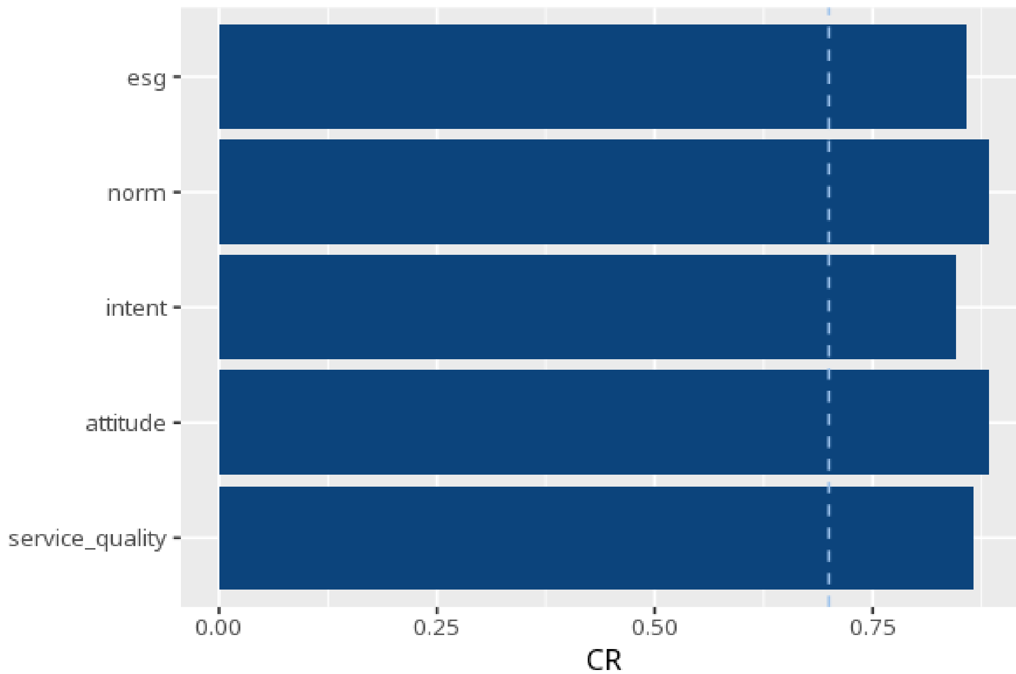
1 Composite reliability (CR)

Construct	CR	AVE	ω	α
esg	.86	.60	.86	.86
norm	.88	.65	.88	.88
intent	.84	.65	.84	.84
attitude	.88	.65	.88	.88
service_quality	.86	.62	.86	.86



CR (Composite Reliability) measures how reliably a set of items captures its construct (0–1); $\geq .70$ is the conventional threshold (Nunnally, 1978; Bagozzi & Yi, 1988). CR is computed from the CFA loadings via semTools::compRelSEM() - for a congeneric (unidimensional) factor CR equals McDonald's ω, so the two columns will always match. AVE is shown alongside for quick convergent-validity reference ($\geq .50$; Fornell & Larcker, 1981) - for the full discriminant-validity assessment (Fornell–Larcker + HTMT matrices) run the AVE card. α (Cronbach's) is a secondary/legacy coefficient - it assumes tau-equivalence (equal loadings) and is a lower bound when loadings differ (McNeish, 2018). All cutoffs are labelled guidelines, not pass/fail gates. Applies to reflective constructs only.

Composite reliability for esg was satisfactory (CR = .86 $\geq$ .70).

Statistical basis: CR (composite reliability) $\geq .70$ acceptable (Nunnally, J. C. (1978). Psychometric Theory (2nd ed.). McGraw-Hill.); CR $\geq .70$ threshold, independent corroboration (Bagozzi, R. P., Yi, Y. (1988). "On the evaluation of structural equation models." Journal of the Academy of Marketing Science, 16(1), 74-94.); AVE shown alongside for convergent-validity reference ($\geq .50$) (Fornell, C., Larcker, D. F. (1981). "Evaluating structural equation models with unobservable variables and measurement error." Journal of Marketing Research, 18(1), 39-50.); α retained as a secondary/legacy coefficient (lower bound when loadings differ) (McNeish, D. (2018). "Thanks coefficient alpha, we'll take it from here." Psychological Methods, 23(3), 412-433.).
