

Results

01 • PAIRED T-TEST

do two related measurements differ?

Table 1. Paired descriptives

Condition	N	M	SD
pre	6	70.33	3.14
post	6	82.33	3.78

Table 2. Paired-samples t-test

Pair	t	df	p	M _{diff}	95% CI	d [95% CI] _z
pre – post	-10.39	5	<.001	-12.00	[-14.97, -9.03]	-4.24 [-6.90, -1.58]

assumption check: normality of the difference scores. (Shapiro-Wilk W=0.92, p=.523)

Figure. Change per case

How to read this test

Tests whether the average change between two related measurements (e.g. before vs. after) differs from zero. A p below alpha means a significant change; the mean difference, CI and dz describe its size (their sign depends on the subtraction order, A–B). A p at or above alpha does not prove there was no change — only that none was detected. Your significance threshold (α) is 0.05.

APA template: A paired-samples t-test gave $M=-12.0$, $t(5)=-10.39$, $p < .001$, $dz=-4.24$ $[-6.90, -1.58]$.
