01 • PEARSON CORRELATION

linear association of two numeric variables

**Table.** Pearson correlation

| Pair                       | r    | 95% CI       | t    | df | p     | N  |
|----------------------------|------|--------------|------|----|-------|----|
| hours_studied – exam_score | 0.70 | [0.50, 0.83] | 6.07 | 38 | <.001 | 40 |

**Figure.** Relationship

**How to read this test**

r ranges from –1 to +1: the sign is the direction, the magnitude the strength (~.1 small, .3 medium, .5 large). p tests whether it differs from zero; the 95% CI shows the precision. r measures only linear association — a strong curved relationship can give r near 0, and r is sensitive to outliers, so always inspect the scatterplot (use Spearman's rs for monotonic-but-nonlinear or outlier-affected data). Correlation does not imply causation. Your significance threshold (α) is 0.05.

**APA template:** hours\_studied and exam\_score were correlated,  $r(38)=.70$ ,  $p < .001$ , 95% CI [0.50, 0.83].
