

1 Chi-square independence

Row \ Column	no	yes	Total
discussion	11 [7.60] (68.8% / 57.9%) r=2.20	5 [8.40] (31.3% / 23.8%) r=-2.20	16
lecture	4 [6.17] (30.8% / 21.1%) r=-1.47	9 [6.83] (69.2% / 42.9%) r=1.47	13
seminar	4 [5.22] (36.4% / 21.1%) r=-0.87	7 [5.78] (63.6% / 33.3%) r=0.87	11
Total	19	21	40

χ^2	df	p	Cramér's V [95% CI]
4.90	2	.086	0.35 [0.00, 1.00]

Tests whether two categorical variables are associated. A p below alpha means they are related; Cramér's V gives the strength of association (0–1); each cell's standardized residual (r) beyond about ± 1.96 flags a category combination that significantly drives the association. Valid only when expected counts are mostly ≥ 5 (the app flags this and suggests Fisher's exact) and each case appears once (raw counts, not percentages). Your significance threshold (α) is 0.05.

A chi-square test of independence gave $\chi^2(2, N=40)=4.90$, $p = .086$, $V=.35$ [0.00, 1.00].
