

# 1 Logistic regression

|                           | Log-odds (B)    | Odds ratio (OR)          |
|---------------------------|-----------------|--------------------------|
| (Intercept)               | −6.59<br>(2.92) | < 0.01<br>[< 0.01, 0.24] |
| pre_score                 | 0.08<br>(0.04)  | 1.08<br>[1.01, 1.18]     |
| age                       | 0.03<br>(0.03)  | 1.03<br>[0.98, 1.09]     |
| group: b                  | 1.24<br>(0.72)  | 3.46<br>[0.87, 15.44]    |
| Num.Obs.                  | 40              |                          |
| Nagelkerke R <sup>2</sup> | 0.28            |                          |
| Omnibus $\chi^2$          | 9.54 (p .023)   |                          |
| Log.Lik.                  | −22.95          |                          |
| AIC                       | 53.91           |                          |
| BIC                       | 60.66           |                          |
| Predicted \ Observed      | no              | yes                      |
| no                        | 13              | 7                        |
| yes                       | 7               | 13                       |

Each predictor's odds ratio tells how the odds of the outcome change per unit ( $>1$  increases,  $<1$  decreases); a term carries weight when its OR confidence interval excludes 1, and the inline omnibus  $\chi^2$  (with its p) tests the model as a whole. Model fit and the ROC/AUC show how well it classifies overall. Your significance threshold ( $\alpha$ ) is 0.05.

Predictor pre\_score was associated with the outcome, OR=1.08, 95% CI [1.01, 1.18], p = .035 (AUC=.76).
